

# THS4031, THS4032 100-MHz LOW-NOISE HIGH-SPEED AMPLIFIERS

SLOS224C – JULY 1999 – REVISED APRIL 2000

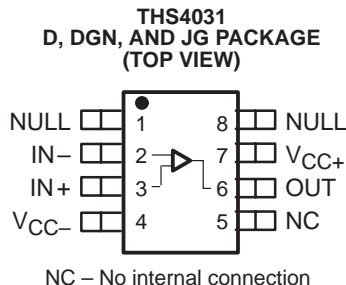

- **Ultra-low  $1.6 \text{ nV}/\sqrt{\text{Hz}}$  Voltage Noise**
- **High Speed**
  - 100 MHz Bandwidth ( $G = 2$  (–1), –3 dB)
  - 100 V/ $\mu\text{s}$  Slew Rate
- **Stable in Gains of 2 (–1) or Greater**
- **Very Low Distortion**
  - THD = –72 dBc ( $f = 1 \text{ MHz}$ ,  $R_L = 150 \Omega$ )
  - THD = –90 dBc ( $f = 1 \text{ MHz}$ ,  $R_L = 1 \text{ k}\Omega$ )
- **Low 0.5 mV (Typ) Input Offset Voltage**
- **90 mA Output Current Drive (Typical)**
- **$\pm 5 \text{ V}$  to  $\pm 15 \text{ V}$  Typical Operation**
- **Available in Standard SOIC, MSOP, PowerPAD™, JG, or FK Package**
- **Evaluation Module Available**

## description

The THS4031 and THS4032 are ultralow-voltage noise, high-speed voltage feedback amplifiers that are ideal for applications requiring low voltage noise, including communication and imaging. The single-amplifier THS4031 and the dual-amplifier THS4032 offer very good ac performance with 100-MHz bandwidth, 100-V/ $\mu\text{s}$  slew rate, and 60-ns settling time (0.1%). The THS4031 and THS4032 are stable at gains of 2 (–1) or greater. These amplifiers have a high drive capability of 90 mA and draw only 8.5-mA supply current per channel. With total harmonic distortion (THD) of –72 dBc at  $f = 1 \text{ MHz}$ , the THS4031 and THS4032 are ideally suited for applications requiring low distortion.

**Figure 2. THS4032 – Dual Channel**

### absolute maximum ratings over operating free-air temperature (unless otherwise noted)<sup>†</sup>

Supply voltage, $V_{CC+}$ to $V_{CC-}$	33 V
Input voltage, $V_I$	$\pm V_{CC}$
Output current, $I_O$	150 mA
Differential input voltage, $V_{IO}$	$\pm 4$ V
Continuous total power dissipation	See Dissipation Rating Table
Operating free-air temperature, $T_A$ :	
C-suffix	0°C to 70°C
I-suffix	-40°C to 85°C
M-suffix	-55°C to 125°C
Maximum junction temperature, $T_J$	150°C
Storage temperature, $T_{stg}$	-65°C to 150°C
Lead temperature 1,6 mm (1/16 inch) from case for 10 seconds	300°C
Lead temperature 1,6 mm (1/16 inch) from case for 60 seconds, JG package	300°C
Case temperature for 60 seconds, FK package	260°C

<sup>†</sup> Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

**DISSIPATION RATING TABLE**

PACKAGE	$\theta_{JA}$ (°C/W)	$\theta_{JC}$ (°C/W)	$T_A = 25^\circ\text{C}$ POWER RATING
D	167 <sup>‡</sup>	38.3	740 mW
DGN <sup>§</sup>	58.4	4.7	2.14 W
JG	119	28	1050 mW
FK	87.7	20	1375 mW

<sup>‡</sup> This data was taken using the JEDEC standard Low-K test PCB. For the JEDEC Proposed High-K test PCB, the  $\theta_{JA}$  is 95°C/W with a power rating at  $T_A = 25^\circ\text{C}$  of 1.32 W.

<sup>§</sup> This data was taken using 2 oz. trace and copper pad that is soldered directly to a 3-in. × 3-in. PC. For further information, refer to *Application Information* section of this data sheet.

## APPLICATION INFORMATION

### theory of operation

The THS403x is a high-speed operational amplifier configured in a voltage feedback architecture. It is built using a 30-V, dielectrically isolated, complementary bipolar process with NPN and PNP transistors possessing  $f_T$ s of several GHz. This results in an exceptionally high-performance amplifier that has a wide bandwidth, high slew rate, fast settling time, and low distortion. A simplified schematic is shown in Figure 43.

Figure 43. THS4031 Simplified Schematic

### noise calculations and noise figure

Noise can cause errors on very small signals. This is especially true when amplifying small signals. The noise model for the THS403x, shown in Figure 44, includes all of the noise sources as follows:

- $e_n$  = Amplifier internal voltage noise ( $nV/\sqrt{Hz}$ )
- $IN+$  = Noninverting current noise ( $pA/\sqrt{Hz}$ )
- $IN-$  = Inverting current noise ( $pA/\sqrt{Hz}$ )
- $e_{RX}$  = Thermal voltage noise associated with each resistor ( $e_{RX} = 4 kTR_X$ )

APPLICATION INFORMATION

noise calculations and noise figure (continued)

Figure 44. Noise Model

The total equivalent input noise density ( $e_{ni}$ ) is calculated by using the following equation:

$$e_{ni} = \sqrt{(e_n)^2 + (IN+ \times R_S)^2 + (IN- \times (R_F \parallel R_G))^2 + 4 kTR_S + 4 kT(R_F \parallel R_G)}$$

Where:

$k$  = Boltzmann's constant =  $1.380658 \times 10^{-23}$

$T$  = Temperature in degrees Kelvin ( $273 + ^\circ\text{C}$ )

$R_F \parallel R_G$  = Parallel resistance of  $R_F$  and  $R_G$

To get the equivalent output noise of the amplifier, just multiply the equivalent input noise density ( $e_{ni}$ ) by the overall amplifier gain ( $A_V$ ).

$$e_{no} = e_{ni} A_V = e_{ni} \left( 1 + \frac{R_F}{R_G} \right) \text{ (Noninverting Case)}$$

As the previous equations show, to keep noise at a minimum, small-value resistors should be used. As the closed-loop gain is increased (by reducing  $R_G$ ), the input noise is reduced considerably because of the parallel resistance term. This leads to the general conclusion that the most dominant noise sources are the source resistor ( $R_S$ ) and the internal amplifier noise voltage ( $e_n$ ). Because noise is summed in a root-mean-squares method, noise sources smaller than 25% of the largest noise source can be effectively ignored. This advantage can greatly simplify the formula and make noise calculations much easier to calculate.

For more information on noise analysis, please refer to the *Noise Analysis* section in *Operational Amplifier Circuits Applications Report* (literature number SLVA043).

APPLICATION INFORMATION

noise calculations and noise figure (continued)

This brings up another noise measurement usually preferred in RF applications, the noise figure (NF). Noise figure is a measure of noise degradation caused by the amplifier. The value of the source resistance must be defined and is typically 50 Ω in RF applications.

$$NF = 10\log \left[ \frac{e_{ni}^2}{(e_{Rs})^2} \right]$$

Because the dominant noise components are generally the source resistance and the internal amplifier noise voltage, we can approximate noise figure as:

$$NF = 10\log \left[ 1 + \frac{\left[ (e_n)^2 + (IN + \times R_S)^2 \right]}{4 kTR_S} \right]$$

Figure 45 shows the noise figure graph for the THS403x.

Figure 45. Noise Figure vs Source Resistance

APPLICATION INFORMATION

optimizing frequency response

Internal frequency compensation of the THS403x was selected to provide very wide bandwidth performance and still maintain a very low noise floor. In order to meet these performance requirements, the THS403x must have a minimum gain of 2 (–1). Because everything is referred to the noninverting terminal of an operational amplifier, the noise gain in a  $G = -1$  configuration is the same as a  $G = 2$  configuration.

One of the keys to maintaining a smooth frequency response, and hence, a stable pulse response, is to pay particular attention to the inverting terminal. Any stray capacitance at this node causes peaking in the frequency response (see Figure 46 and Figure 47). Two things can be done to help minimize this effect. The first is to simply remove any ground planes under the inverting terminal of the amplifier, including the trace that connects to this terminal. Additionally, the length of this trace should be minimized. The capacitance at this node causes a lag in the voltage being fed back due to the charging and discharging of the stray capacitance. If this lag becomes too long, the amplifier will not be able to correctly keep the noninverting terminal voltage at the same potential as the inverting terminal's voltage. Peaking and possible oscillations will then occur if this happens.

Figure 46

Figure 47

The second precaution to help maintain a smooth frequency response is to keep the feedback resistor ( $R_f$ ) and the gain resistor ( $R_g$ ) values fairly low. These two resistors are effectively in parallel when looking at the ac small-signal response. This is why in Figure 30, a feedback resistor of 3.9 k $\Omega$  with a gain resistor of 1 k $\Omega$  only shows a small peaking in the frequency response. The parallel resistance is only 800  $\Omega$ . This value, in conjunction with a very small stray capacitance test PCB, forms a zero on the edge of the amplifier's natural frequency response. To eliminate this peaking, all that needs to be done is to reduce the feedback and gain resistances. One other way to compensate for this stray capacitance is to add a small capacitor in parallel with the feedback resistor. This helps to neutralize the effects of the stray capacitance. To keep this peaking out of the operating range, the stray capacitance and resistor value's time constant must be kept low. But, as can be seen in Figures 26 – 29, a value too low starts to reduce the bandwidth of the amplifier. Table 1 shows some recommended feedback resistors to be used with the THS403x.

---

APPLICATION INFORMATION

optimizing frequency response (continued)

-1	360 $\Omega$
5	3.3 k $\Omega$ (low stray-c PCB only)

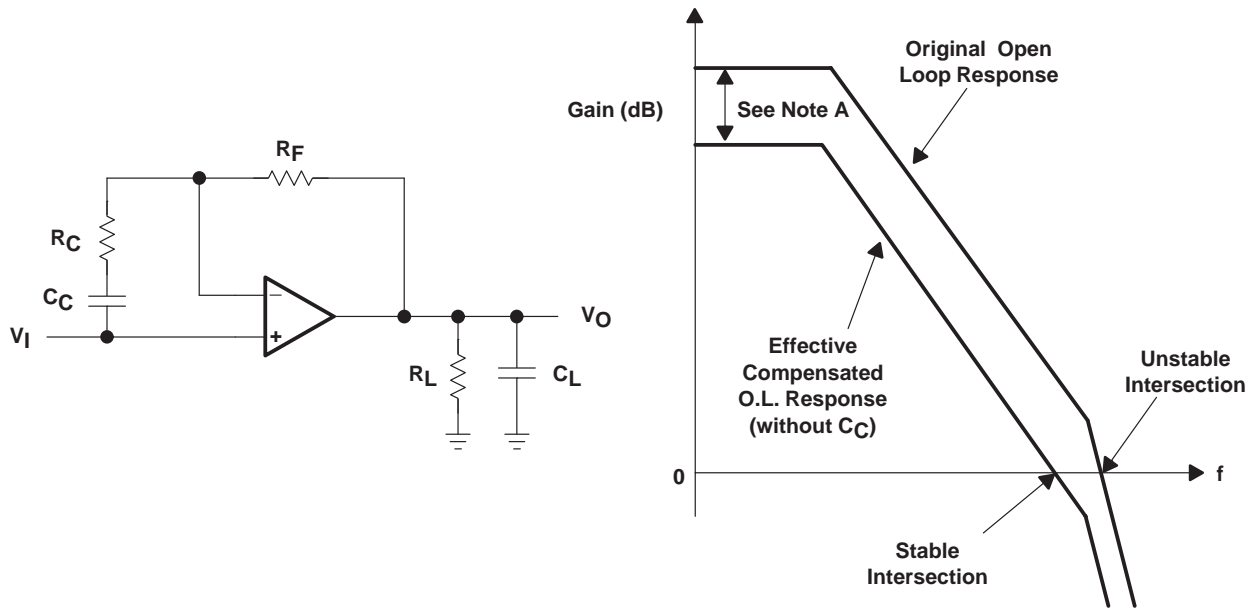

unity-gain concerns

THS403x was designed for extremely low noise with a minimum gain of 2 (-1). If the amplifier were to be configured for unity gain, the output would tend to oscillate because the open-loop intersection on a Bode diagram is at a -40 dB/decade slope instead of the -20 dB/decade slope required for stable operation. But, it is sometimes desirable to have a low-noise unity gain buffer. There is a way to accomplish this feat with the THS403x with some added complexity (see Figure 48). The lag compensation circuit shown in Figure 48 increases the noise gain of the amplifier without increasing the signal gain. Another way to look at this is that the open-loop gain is effectively reduced by the  $1 + R_f/R_C$  gain. This reduction causes the -40 dB/decade pole to be shifted down into an open-loop gain of less than 1. The drawbacks of this circuit are the decreased frequency response, the increased noise, and the increased output offset voltage ( $V_{OO}$ ). One way to eliminate the  $V_{OO}$  increase is to add a capacitor ( $C_C$ ) in series with  $R_C$ , with the added requirement that the time constant of  $C_C$  and  $R_C$  be set low enough for the Bode plot intersection to be at a -20 dB/decade slope. Typically, a  $1 + R_f/R_C$  gain of 2 to 3 yields a smooth frequency response for the THS403x. If  $C_C$  is used, it is desirable to have the  $1/(2\pi R_C C_C)$  frequency 5 to 10 times lower than the amplifier's natural bandwidth. One additional advantage this circuit provides is that it makes driving capacitive loads much easier. A capacitive load causes the -40 dB/decade intersection (because of the phase lag), to be above unity gain, the same as described previously. In general, this  $R_C$  and  $C_C$  modification can be used in both an inverting and noninverting configuration with the same results.

APPLICATION INFORMATION

unity-gain concerns (continued)

NOTE A: The difference is due to  $1+R_F/R_C$  noise gain.

Figure 48. Unity Gain Compensation

driving a capacitive load

Driving capacitive loads with high-performance amplifiers is not a problem as long as certain precautions are taken. The first is to realize that the THS403x has been internally compensated to maximize its bandwidth and slew-rate performance. When the amplifier is compensated in this manner, capacitive loading directly on the output will decrease the phase margin of the device leading to high-frequency ringing or oscillations. Therefore, for capacitive loads of greater than 10 pF, it is recommended that a resistor be placed in series with the output of the amplifier, as shown in Figure 49. A minimum value of 20 Ω should work well for most applications. For example, in 75-Ω transmission systems, setting the series resistor value to 75 Ω both isolates any capacitance loading and provides the proper line impedance matching at the source end.

Figure 49. Driving a Capacitive Load

## APPLICATION INFORMATION

### offset nulling

The THS403x has very low input offset voltage for a high speed amplifier. However, if additional correction is required, the designer can make use of an offset nulling function provided on the THS4031. By placing a potentiometer between terminals 1 and 8 of the device and tying the wiper to the negative supply, the input offset can be adjusted. This is shown in Figure 50.

Figure 50. Offset Nulling Schematic

### offset voltage

The output offset voltage ( $V_{OO}$ ) is the sum of the input offset voltage ( $V_{IO}$ ) and both input bias currents ( $I_{IB}$ ) times the corresponding gains. The following schematic and formula can be used to calculate the output offset voltage:

Figure 51. Output Offset Voltage Model

APPLICATION INFORMATION

general configurations

When receiving low-level signals, limiting the bandwidth of the incoming signals into the system is often required. The simplest way to accomplish this is to place an RC filter at the noninverting terminal of the amplifier (see Figure 52).

Figure 52. Single-Pole Low-Pass Filter

If even more attenuation is needed, a multiple-pole filter is required. The Sallen-Key filter can be used for this task. For best results, the amplifier should have a bandwidth that is 8 to 10 times the filter frequency bandwidth. Otherwise, phase shift of the amplifier can occur.

Figure 53. 2-Pole Low-Pass Sallen-Key Filter

## APPLICATION INFORMATION

### circuit-layout considerations

In order to achieve the levels of high-frequency performance of the THS403x, it is essential that proper printed-circuit board high-frequency design techniques be followed. A general set of guidelines is given below. In addition, a THS403x evaluation board is available to use as a guide for layout or for evaluating the device performance.

- Ground planes – It is highly recommended that a ground plane be used on the board to provide all components with a low inductive ground connection. However, in the areas of the amplifier inputs and output, the ground plane can be removed to minimize the stray capacitance.
- Proper power-supply decoupling – Use a 6.8- $\mu$ F tantalum capacitor in parallel with a 0.1- $\mu$ F ceramic capacitor on each supply terminal. It may be possible to share the tantalum among several amplifiers depending on the application, but a 0.1- $\mu$ F ceramic capacitor should always be used on the supply terminal of every amplifier. In addition, the 0.1- $\mu$ F capacitor should be placed as close as possible to the supply terminal. As this distance increases, the inductance in the connecting trace makes the capacitor less effective. The designer should strive for distances of less than 0.1 inch between the device power terminals and the ceramic capacitors.
- Sockets – Sockets are not recommended for high-speed operational amplifiers. The additional lead inductance in the socket pins will often lead to stability problems. Surface-mount packages soldered directly to the printed-circuit board is the best implementation.
- Short trace runs/compact part placements – Optimum high-frequency performance is achieved when stray series inductance has been minimized. To realize this, the circuit layout should be made as compact as possible, thereby minimizing the length of all trace runs. Particular attention should be paid to the inverting input of the amplifier. Its length should be kept as short as possible. This will help to minimize stray capacitance at the input of the amplifier.
- Surface-mount passive components – Using surface-mount passive components is recommended for high-frequency amplifier circuits for several reasons. First, because of the extremely low lead inductance of surface-mount components, the problem with stray series inductance is greatly reduced. Second, the small size of surface-mount components naturally leads to a more compact layout thereby minimizing both stray inductance and capacitance. If leaded components are used, it is recommended that the lead lengths be kept as short as possible.

### general PowerPAD™ design considerations

The THS403x is available in a thermally enhanced DGN package, which is a member of the PowerPAD™ family of packages. This package is constructed using a downset leadframe upon which the die is mounted [see Figure 54(a) and Figure 54(b)]. This arrangement results in the leadframe being exposed as a thermal pad on the underside of the package [see Figure 54(c)]. Because this thermal pad has direct thermal contact with the die, excellent thermal performance can be achieved by providing a good thermal path away from the thermal pad.

The PowerPAD package allows for both assembly and thermal management in one manufacturing operation. During the surface-mount solder operation (when the leads are being soldered), the thermal pad can also be soldered to a copper area underneath the package. Through the use of thermal paths within this copper area, heat can be conducted away from the package into either a ground plane or other heat-dissipating device.

The PowerPAD™ package represents a breakthrough in combining the small area and ease of assembly of surface mount with the heretofore awkward mechanical methods of heatsinking.

## APPLICATION INFORMATION

### general PowerPAD™ design considerations (continued)

NOTE B: The thermal pad is electrically isolated from all terminals in the package.

**Figure 54. Views of Thermally Enhanced DGN Package**

Although there are many ways to properly heatsink this device, the following steps illustrate the recommended approach.

**Figure 55. PowerPAD™ PCB Etch and Via Pattern**

1. Prepare the PCB with a top-side etch pattern as shown in Figure 55. There should be etch for the leads as well as etch for the thermal pad.
2. Place five holes in the area of the thermal pad. These holes should be 13 mils in diameter. They are kept small so that solder wicking through the holes is not a problem during reflow.
3. Additional vias may be placed anywhere along the thermal plane outside of the thermal pad area. This helps dissipate the heat generated by the THS403xDGN IC. These additional vias may be larger than the 13-mil diameter vias directly under the thermal pad. They can be larger because they are not in the thermal pad area to be soldered so that wicking is not a problem.
4. Connect all holes to the internal ground plane.
5. When connecting these holes to the ground plane, *do not* use the typical web or spoke via connection methodology. Web connections have a high thermal-resistance connection that is useful for slowing the heat transfer during soldering operations. This makes the soldering of vias that have plane connections easier. In this application, however, low thermal resistance is desired for the most efficient heat transfer. Therefore, the holes under the THS403xDGN package should connect to the internal ground plane with a complete connection around the entire circumference of the plated-through hole.
6. The top-side solder mask should leave the terminals of the package and the thermal pad area with its five holes exposed. The bottom-side solder mask should cover the five holes of the thermal pad area, which prevents solder from being pulled away from the thermal pad area during the reflow process.
7. Apply solder paste to the exposed thermal pad area and to all the IC terminals.
8. With these preparatory steps in place, the THS403xDGN IC is simply placed in position and run through the solder reflow operation as any standard surface-mount component. This results in a part that is properly installed.

**APPLICATION INFORMATION**

**general PowerPAD™ design considerations (continued)**

The actual thermal performance achieved with the THS403xDGN in its PowerPAD™ package depends on the application. In the example above, if the size of the internal ground plane is approximately 3 inches × 3 inches, then the expected thermal coefficient,  $\theta_{JA}$ , is about 58.4 °C/W. For comparison, the non-PowerPAD™ version of the THS403x IC (SOIC) is shown. For a given  $\theta_{JA}$ , the maximum power dissipation is shown in Figure 56 and is calculated by the following formula:

$$P_D = \left( \frac{T_{MAX} - T_A}{\theta_{JA}} \right)$$

Where:

- $P_D$  = Maximum power dissipation of THS403x IC (watts)
- $T_{MAX}$  = Absolute maximum junction temperature (150°C)
- $T_A$  = Free-ambient air temperature (°C)
- $\theta_{JA} = \theta_{JC} + \theta_{CA}$
- $\theta_{JC}$  = Thermal coefficient from junction to case
- $\theta_{CA}$  = Thermal coefficient from case to ambient air (°C/W)

NOTE A: Results are with no air flow and PCB size = 3"× 3"

**Figure 56. Maximum Power Dissipation vs Free-Air Temperature**

More complete details of the PowerPAD™ installation process and thermal management techniques can be found in the Texas Instruments technical brief, *PowerPAD™ Thermally Enhanced Package*. This document can be found at the TI web site ([www.ti.com](http://www.ti.com)) by searching on the key word PowerPAD™. The document can also be ordered through your local TI sales office. Refer to literature number SLMA002 when ordering.

APPLICATION INFORMATION

general PowerPAD™ design considerations (continued)

The next thing to be considered is package constraints. The two sources of heat within an amplifier are quiescent power and output power. The designer should never forget about the quiescent heat generated within the device, especially multi-amplifier devices. Because these devices have linear output stages (Class A-B), most of the heat dissipation is at low output voltages with high output currents. Figure 57 to Figure 60 shows this effect, along with the quiescent heat, with an ambient air temperature of 50°C. When using  $V_{CC} = \pm 5\text{ V}$ , heat is generally not a problem, even with SOIC packages. But, when using  $V_{CC} = \pm 15\text{ V}$ , the SOIC package is severely limited in the amount of heat it can dissipate. The other key factor when looking at these graphs is how the devices are mounted on the PCB. The PowerPAD™ devices are extremely useful for heat dissipation. But, the device should always be soldered to a copper plane to fully use the heat dissipation properties of the PowerPAD™. The SOIC package, on the other hand, is highly dependent on how it is mounted on the PCB. As more trace and copper area is placed around the device,  $\theta_{JA}$  decreases and the heat dissipation capability increases. The currents and voltages shown in these graphs are for the total package. For the dual amplifier package (THS4032), the sum of the RMS output currents and voltages should be used to choose the proper package.

<sup>(1)</sup> The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS) or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

<sup>(3)</sup> MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.
